a. Analytical Solution

Given problem	$u_t = u_{xx}$
Domain	$x = [0, 1]$
Boundary condition	$u(0, t) = u(1, t), \quad u_x(0, t) = u_x(1, t)$
Initial condition	$u(x, 0) = \sin(2\pi x)$

The given problem is a well posed homogenous linear PDE and has a unique solution for the given boundary (Neumann) and initial conditions.

The solution is derived as follows by variable separation:

$$\begin{aligned} \text{Let } u(x, t) &= X(x) * T(t) \\ u_t = u_{xx} &\implies XT_t = X_{xx}T \\ \frac{X_{xx}}{X} &= \frac{T_t}{T} = \alpha \end{aligned}$$

(α is a constant since LHS is only a function of x and RHS is a function of t)

$$\begin{aligned} \text{Case 1: } \alpha &= 0 \\ \implies X &= ax + b, \quad T = c \\ \implies u^{\alpha=0} &= a_1x + a_2 \\ \text{Case 2: } \alpha &= \beta^2 > 0 \\ \implies X &= ae^{\beta x} + be^{-\beta x}, \quad T = ce^{\beta^2 t^2} \\ \implies u^{\alpha>0} &= (b_1e^{\beta x} + b_2e^{-\beta x})e^{\beta^2 t^2} \end{aligned}$$

where b_1 and b_2 are arbitrary constants depending on β

$$\begin{aligned}
\text{Case 3: } & \alpha = -\lambda^2 < 0 \\
\implies & X = a \cos(\lambda x) + b \sin(\lambda x), \quad T = ce^{-\lambda^2 t^2} \\
\implies & u^{\alpha < 0} = (c_1 \cos(\lambda x) + c_2 \sin(\lambda x))e^{-\lambda^2 t^2}
\end{aligned}$$

where c_1 and c_2 are arbitrary constants depending on λ

Due to the homogenous and linear nature of the given PDE, the solution is given by a finite combination of solution of above 3 cases. It can be also proved that the solution is true for a countable series consisting of above 3 solutions. However we would not delve into this topic. For our initial problem, it is enough to consider case 3.

$$u(x, t) = ((c_1 \cos(\lambda x) + c_2 \sin(\lambda x))e^{-\lambda^2 t^2}) \quad (1)$$

Applying boundary condition $u(0, t) = u(1, t)$, we get

$$c_1(\cos(\lambda) - 1) + c_2 \sin(\lambda) = 0 \quad (2)$$

Applying boundary condition $u_x(0, t) = u_x(1, t)$ and the fact that $\lambda \neq 0$, we get

$$c_1(\lambda) \sin(\lambda) + c_2(\lambda)(1 - \cos(\lambda)) = 0 \quad (3)$$

Solving equations 2 and 3, we get the following two equations

$$c_1 = c_2 = 0 \quad (4)$$

The above equation leads to a trivial solution and does not satisfy the given initial condition. Hence the following must hold

$$\sin(\lambda) = (1 - \cos(\lambda)) = 0 \quad (5)$$

The above equation is satisfied if and only if,

$$\lambda = n\pi, \text{ where } n \in \mathbb{Z} - \{0\} \quad (6)$$

For the given initial condition $u(x, 0) = \sin(2\pi x)$, we get

$$c_1 = 0 \quad (7)$$

$$\lambda = 2\pi \quad (8)$$

$$c_2 = 1 \quad (9)$$

Thus the analytical solution is given by

$$u(x, t) = \sin(2\pi x)e^{(-4\pi^2 t^2)} \quad (10)$$

The above solution satisfies the PDE, initial and boundary conditions. Moreover due to well posed nature of the problem, the solution obtained is a unique one (by maximum energy principle).

b. Numerical Scheme

$$u_t = u_{xx}$$

The following is the explicit Euler (time derivative) and second order central difference (space derivative) scheme

$$u_i^{t+1} = u_i^t + \frac{\Delta t}{(\Delta x)^2}(u_{i+1}^t - 2u_i^t + u_{i-1}^t) \quad (11)$$

The above equation can be used to obtain the value at next time step for every internal point. For the end points, the following equations are used due to periodic boundary conditions,

$$u_0^{t+1} = u_0^t + \frac{\Delta t}{(\Delta x)^2}(u_1^t - 2u_0^t + u_{endpoint-1}^t) \quad (12)$$

$$u_{endpoint}^{t+1} = u_0^{t+1} \quad (13)$$

Since $\Delta t = 0.00001$, the maximum number of grid points allowed is 223 due to convergence and stability criteria, $\Delta t \leq \frac{1}{2}(\Delta x)^2$

c. Numerical simulations

A code is written in C language and given in Appendix A. It uses command line arguments for input of Number of grid points and Time step at which solution is required. Please compile it using a suitable compiler (GCC) as follows

```
gcc code.c -o "output file name"  
"output file name".exe "Number of grid points" "Time step(s)"
```

For example,

```
gcc code.c -o results  
results.exe 200 300 500 1000
```

The above example inputs 200 as the number of grid points and prints the numerical and analytical solutions at 300, 500 and 1000 time steps.

Note: The maximum number of grid points (default:128) the code accepts is 220 (for convergence) and the maximum time step (default: 0, 100, 500 and 1000) is 3000 and number of time step arguments (default:4) is 10.

d. Solution Plot for 128 grid points

- e. Average Error in the Domain at each time step
